## Engineering Bulletin: Preseupe Dpop in Pipes

It is a common misconception that the velocity of air exiting an air knife is the most important performance measurement. What really is the most important is how much Fluid Power is available at the air knife.

## Fluid Power = Flow Rate * Pressure

To achieve the highest Fluid Power, it is critical to minimize the pressure drop in piping between the blower and the target.

## Best Practices for Minimizing Pressure Drops

- Position the blower as close as possible to the target.
- Use large size piping, equal to the blower discharge or larger
- Use as few elbows as possible. When needed, use long sweep elbows. Short elbows are not recommended.
- Use hard pipe with smooth interior walls, such as PVC pipe or Stainless Steel thin wall tubing. Flexible hose connections should be minimized.
- Use the appropriate pipe connections such as Paxton Zero Loss Adapters
- Use well designed dividers with smooth transitions
- Only use flexible hose at the end of the piping system to connect the air knifes or manifolds. Smooth tubing typically has 70\% less pressure drop. Avoid kinks in the hoses or sharp bends - these will lead to high pressure drops.
- High velocity air tends to do better when traveling straight or around smooth transitions. Avoid going over sharp corners or edges.
- One last tip, how do you know if the system is OK? The best measurement is to use a Differential Pressure gauge to measure a pressure difference between the blower outlet and the end of the air knife or manifold. This is exactly what the Paxton Engineers do when they install systems.

## How to Calculate Pressure Drops

There are many factors that go into calculating pressure drop in a blower-driven system, including air flow rate, temperature, pipe geometry (ID), and the interior smoothness of the pipe. This Technical Bulletin is intended to help design piping systems in the field. If your piping distances are long, or you need help, please contact us.

PVC pipe is used for example purposes in this Bulletin. Thin wall stainless steel tubing works well also, and is similar in pressure drop.

## Engineering 圆ulletin: Pressure Drop in Pipes

Example: Paxton AT-1200 Blower, producing 750 CFM @ 70 inches of water column pressure (US Units) or $1200 \mathrm{~m}^{3} / \mathrm{hr} @ 174 \mathrm{mbar}$ pressure (Metric) operating three (3) Air Knives.

Including a Paxton 3 way Divider and Paxton 4in PVC Adapters.

## System Piping:

(US 5 feet)/(Metric 2m) of 4 inch Schedule 40 (white) PVC pipe $2 \times 90$ Degree Long Sweep Elbows (4 inch PVC Pipe, Schedule 40) $3 \times$ Flexible hoses, 3 inch ID x 3 feet long each

## How much pressure drop will the system have?

## AIR KNIVES

250 CFM @ 61.5 W/C (ea) $400 \mathrm{~m}^{3} / \mathrm{hr}$ @ 154mbar (ea)

| Type | Pipe Diameter | Pressure Drop Per Table | Multiplier | Total Pressure Drop*, in W/C / in mbar |
| :---: | :---: | :---: | :---: | :---: |
| Straight PVC | 4 inch | 0.42 per ft 2.95 mbar per $m$ | 5 feet <br> 2 meters | $\begin{aligned} & 2.1 \\ & 5.9 \end{aligned}$ |
| Elbow | 4 inch | 1.97 each 4.59 mbar each | $2$ | $\begin{aligned} & 3.9 \\ & 9.2 \end{aligned}$ |
| Flex Hose | 3 inch | 0.83 per ft <br> 5.89 mbar per m | 3 feet <br> 1 meter | $\begin{aligned} & 2.5 \\ & 5.9 \end{aligned}$ |
| *Actual pressure drop is expected to be less, as this method employs safety factors and approximations. |  |  |  | 8.5 inches of water column 21.0 mbar |

## So, the performance at the Air Knives will each be:

250 CFM at 61.5" W/C. (70 in W/C at blower - 8.5 in W/C pressure drop) or $1200 \mathrm{~m}^{3} / \mathrm{hr} @ 154 \mathrm{mbar}$.

## To Calculate the Fluid Power:

| Units | Fluid Power in hp/kWN | Power at Blower | Power at each Air Knife |
| :---: | :---: | :---: | :---: |
| US | cfm*pressure $\div 6643$ | $750 \mathrm{cfm}^{*} 70$ inch of water column $=8.28 \mathrm{hp}$ | $750 \mathrm{cfm} \div 3^{*}(70-8.5)$ inch of water column $\div 6343$ <br> $=2.42 \mathrm{hp}$ |
| Metric | $\mathrm{m}^{3} / \mathrm{hr}^{*} \mathrm{mbar} \div 35984$ | $1200 \mathrm{~m}^{3} / \mathrm{hr} * 175 \mathrm{mbar} \div 35984=5.84 \mathrm{~kW}$ | $1200 \mathrm{~m}^{3} / \mathrm{hr} \div 3^{*}(175-21.0) \mathrm{mbar} \div 35984$ <br> $=1.65 \mathrm{~kW}$ |
